## Abstract

We present derivation proof procedures for extended stable model semantics. Given program  $\Pi$  and goal  $G$ ,  $G$  belongs to the well founded model of  $\Pi$  iff there is a *WFM*-derivation for  $G$  in  $\Pi$ . Likewise, given program  $\Pi$  and goal  $G$ ,  $G$  belongs to some extended stable model of  $\Pi$  iff there is a *XSM*-derivation for  $G$  in  $\Pi$ . Correctness (completeness and soundness) of these procedures is discussed. Example derivations are exhibited, as well as a simple Prolog implementation that directly mirrors the procedures.

## 1 Introduction

Well Founded Semantics (*WFS*) [Van Gelder *et al.*, 1990] adequately captures various forms of hypothetical reasoning [Pereira *et al.*, 1991c, Pereira *et al.*, 1991d, Pereira *et al.*, 1991b, Pereira *et al.*, 1991a] if we interpret the well-founded model (*WFM*) of a program  $\Pi$  as a (possibly incomplete) core view of the world, the extended stable models (*XSMs*) specifying alternative complementary consistent views of the world, all of each containing the core *WFM*.

The paper is organized as follows: in section 2 we review well founded semantics. In section 3 we define *WFM*-derivations, discuss their correctness, and give examples. Next, in section 4, we define *XSM*-derivations and discuss their correctness. Finally, in section 5, a Prolog implementation is produced, directly reflecting the derivation procedures mentioned. More details can be found in an extended version of this paper [Pereira *et al.*, 1990].

By a logic program  $\Pi$  we mean a finite set of universally closed rules of the form:  $H \leftarrow L_1, \dots, L_n$  where  $n \geq 0$ ,  $H$  is an atom and the  $L_i$ 's are literals. When  $n = 0$ , we also write  $H \leftarrow \mathbf{t}$ , where  $\mathbf{t}$  stands for an atom satisfied in all models. Negative literals are expressed as  $\sim A$  where  $A$  is an atom. We denote by  $\text{Lit}(\Pi)$  the set of literals in  $\text{ground}(\Pi)$ , the Herbrand instantiation of program  $\Pi$ . We denote the well founded model of a program  $\Pi$  by  $WFM(\Pi)$ , and an extended stable model (which may be the well founded one) by  $XSM(\Pi)$ .

## 2 The Extended Stable Model Semantics

In this section we characterize the Well Founded and Extended Stable Models of a program, based on [Przymusinska and Przymusinski, 1990]. Alternative definitions of the Well Founded Semantics can be found in [Van Gelder *et al.*, 1990] or in [Przymusinski, 1989]. Because the semantics is 3-valued, we begin by defining 3-valued interpretations.

**Definition 2.1** A 3-valued Herbrand interpretation  $I$  of a first-order language  $L$  is any pair  $\langle T; F \rangle$ , where  $T$  and  $F$  are disjoint subsets of the Herbrand base  $H$ .  $T$  contains all ground atoms true in  $I$ ,  $F$  contains all ground atoms false in  $I$ , and the truth value of the remaining atoms, those in  $U = H - (T \cup F)$ , is undefined (or unknown).

An alternative way to represent an interpretation  $I = \langle T; F \rangle$  is  $I = T \cup \{\sim L \mid L \in F\}$ .

**Proposition 2.1** Any interpretation  $I = \langle T; F \rangle$  can be equivalently viewed as a function  $I : H \rightarrow V$  where  $V = \{0, 1/2, 1\}$ , defined by:

- $I(A) = 0$  if  $A \in F$
- $I(A) = 1/2$  if  $A \in U$
- $I(A) = 1$  if  $A \in T$

**Definition 2.2** The function  $I : H \rightarrow V$  can be recursively extended to the truth valuation function  $\hat{i} : \text{Lit}(\Pi) \rightarrow V$  defined on the set  $\text{Lit}(\Pi)$  of all literals of the language as follows, where  $A$  is a ground atom:

- $\hat{i}(A) = I(A)$
- $\hat{i}(\sim A) = 1 - I(A)$

**Definition 2.3** A non-negative program is a program whose premises are either positive atoms or the special proposition  $\mathbf{u}$ . Every interpretation  $I$  satisfies  $I(\mathbf{u}) = 1/2$ , and so  $\hat{i}(\sim \mathbf{u}) = 1/2$ .  $\mathbf{u}$  denotes the undefined (or unknown) value.

**Theorem 2.1** (*Generalization of [Van Emden and Kowalski, 1976]*) Every non negative logic-program has a unique least<sup>1</sup> 3-valued model.

<sup>1</sup>If  $I$  and  $J$  are two interpretations then we say that  $I \leq J$  if  $I(A) \leq J(A)$  for any ground atom  $A$ . If  $\mathcal{I}$  is a

Next we define the program transformation  $\Pi/M$  ( $\Pi$  modulo  $M$ ), which is a 3-valued extension to the 2-valued transformation in [Gelfond and Lifschitz, 1988].

**Definition 2.4** Let  $\Pi$  be a logic program and let  $I$  be a 3-valued interpretation. By the *extended GL-transformation of  $\Pi$  modulo  $I$*  we mean a new (non-negative) program  $\Pi/I$  obtained from  $\Pi$  by performing the following three operations:

- Removing from  $\Pi$  all rules which contain a negative premise  $L = \sim A$  such that  $\hat{i}(L) = 0$ .
- Replacing in all remaining rules those negative premises  $L = \sim A$  which satisfy  $\hat{i}(L) = 1/2$  by  $\mathbf{u}$ .
- Removing from all the remaining rules those negative  $L = \sim A$  which satisfy  $\hat{i}(L) = 1$ .

Since the resulting program  $\Pi/I$  is non-negative, by theorem 2.5, it has a unique least 3 valued model. We define  $\Gamma^*(I)$  (a generalization of the  $\Gamma$  operator [Gelfond and Lifschitz, 1988]) to be the 3-valued least model of  $\Pi/I$ .

**Definition 2.5** A 3-valued interpretation  $I$  of a logic program  $\Pi$  is called an *Extended Stable Model XSM* of  $\Pi$  iff  $\Gamma^*(I) = I$ .

In order to check if  $I$  is an XSM of a program we give a constructive definition of  $\Gamma^*$  operator. For this purpose we define  $\Psi^*$ , a generalization of the Van Emden-Kowalski operator  $\Psi$ .

**Definition 2.6** Let  $\Pi$  be a non-negative program,  $I$  an interpretation of  $\Pi$  and  $A$  is a ground atom. Then  $\Psi^*(I)$  is an interpretation defined as follows:

- $\Psi^*(I)(A) = 1$  iff there is a rule  $A \leftarrow A_1, \dots, A_n$  in  $\Pi$  such that  $I(A_i) = 1$  for all  $i \leq n$ .
- $\Psi^*(I)(A) = 0$  iff for every rule  $A \leftarrow A_1, \dots, A_n$  in  $\Pi$  there is an  $i \leq n$  such that  $I(A_i) = 0$ .
- $\Psi^*(I)(A) = 1/2$ , otherwise

We define  $\Psi^{*\uparrow n} = \Psi^*(\Psi^{*\uparrow n-1})$  and  $\Psi^{*\uparrow 0} = \langle \{\}, H \rangle$

**Definition 2.7** Let  $I$  be an interpretation and  $\Pi$  a logic program.  $\Gamma^*(I)$  for  $\Pi$  can be defined as  $\Gamma^*(I) = \Psi^{*\uparrow w}(\Pi/I)$ .

This alternative definition of the *WF* semantics was proved equivalent to the original one [Van Gelder *et al.*, 1990] in [Przymusinska and Przymusinski, 1990] by the following theorem:

**Theorem 2.2** The Well Founded Model of a program  $\Pi$  is the  $F$ -least<sup>2</sup> Extended Stable Model of  $\Pi$ . Consequently the *WFS* coincides with the *XSMS*.

collection of interpretations, then an interpretation  $I \in \mathcal{I}$  is called minimal in  $\mathcal{I}$  if there is no interpretation  $J \in \mathcal{I}$  such that  $J \leq I$  and  $I \neq J$ . An interpretation  $I$  is called least in  $\mathcal{I}$  if  $I \leq J$ , for any other interpretation  $J \in \mathcal{I}$ . A model of a theory  $R$  is called minimal (resp. least) if it is minimal (resp. least) among all models of  $R$ .

<sup>2</sup>If  $I = \langle T, F \rangle$  and  $I' = \langle T', F' \rangle$  are two interpretations, then we say that  $I \leq_F I'$  iff  $T \subseteq T'$  and  $F \subseteq F'$ . An interpretation  $I$  is called  $F$ -least in a collection of interpretations  $\mathcal{I}$  if  $I \leq_F J$  for any interpretation  $J \in \mathcal{I}$  [Fitting, 1985]

To obtain a constructive definition of the *WFM* of a program  $\Pi$  we use the following sequence of  $\{I_\alpha\}$  of interpretations of  $\Pi$ :

- $I_0 = \langle \{\}, \{\} \rangle$
- $I_{\alpha+1} = \Gamma^*(I_\alpha)$

The *WF* model of  $\Pi$  is the least fixed point of this sequence, i.e.  $I_\lambda$  [Przymusinska and Przymusinski, 1990].

### 3 Derivation Procedure for the Well Founded Model

Now we present a derivation procedure such that given a program  $\Pi$  and a goal  $G$  the derivation succeeds iff  $G$  is in *WFM*( $\Pi$ ). The procedure is defined over the ground instance of  $\Pi$ , the set of all ground instances of the rules in  $\Pi$  with respect to its Herbrand Universe. Without loss of generality we can assume that  $\Pi$  has been already *instantiated* and thus consists of a (possibly infinite) set of propositional rules.

**Definition 3.1** A *positive* (resp. *negative*) interpretation  $I$  is a set of positive (resp. negative) literals from  $\text{Lit}(\Pi)$ .

**Definition 3.2** A *context*  $C_n$  is an ordered set of positive or negative interpretations. Let  $S_i$  be a positive or a negative interpretation;  $C_n$  denotes the context  $S_1 S_2 \dots S_n$ .  $C_n$  is a *negative* (resp. *positive*) context if  $S_n$  is a negative interpretation (resp. positive interpretation).  $C_n + G$  denotes the concatenation  $S_1 S_2 \dots S_n G$ . A literal  $G$  is in context  $C_n$  ( $G \in C_n$  for short)  $G \in S_n$ .

A context  $C_n$  implicitly defines an interpretation  $I_n(C_n)$  which is the set of literals in partial interpretations  $S_n$  i.e.  $I_n(C_n) = \cup_{(i \leq n)} S_i$ , and for no atom  $A$  both  $A$  and  $\sim A$  belong to it.

**Definition 3.3** A *contextual formula* ( $C$ -formula) is a pair  $C \# F$ , where  $C$  is a context and  $F$  is an expression built from atoms with conjunctions and negations. An empty  $C$ -formula is the  $C$ -formula  $C \# \mathbf{t}$ .

By the interpretation  $I(C \# F)$  we mean the interpretation  $I(C)$  associated with context  $C$ .

**Definition 3.4 (WFM-derivation)** Let

$R_j = \langle C_j \# F_j; I_j \rangle$  where  $C_j$  is a context, and  $I_j$  a set of literals. A *WFM-derivation* from  $R_i$  to  $R_n$  is a sequence from  $\langle C_i \# F_i; I_i \rangle$  to  $\langle C_n \# F_n; I_n \rangle$  such that for any  $\langle C_k \# F_k; I_k \rangle$  ( $i \leq k \leq n$ ), the following derivation rules apply (where we assume  $C_{k+1} = C_k$  and  $I_{k+1} = I_k$  unless stated otherwise).

**D1.1.** if  $F_k = \sim G$  and there is no rule  $G \leftarrow B$  then  $R_{k+1} = \langle C_k + \sim G \# \mathbf{t}; I_k \cup \{\sim G\} \rangle$ .

**D1.2.** if  $F_k = \sim G$  and  $\sim G \in C_k$  then  $R_{k+1} = \mathbf{t}$ .

**D2.1.** if  $F_k = \sim G$  and there are  $r$  rules for  $G$  with  $G_i$  ( $1 \leq i \leq r$ ) as head,  $\sim G \notin C_k$ ,  $G \notin I_k$

$$G_1 \leftarrow B_{11}, \dots, B_{m1}$$

$$\vdots$$

$$G_r \leftarrow B_{1r}, \dots, B_{m'r}$$

in  $\Pi$  and  $G \notin I_k$ , then

$R_{k+1} = \langle C_k + \sim G \# \tilde{G}_1, \dots, \tilde{G}_r; I_k \cup \{\sim G\} \rangle$  where  $\tilde{G}_i$  is a short hand for  $\sim(B_{1i}, \dots, B_{mi})$

**D2.2.** if  $F_k = \sim(G_1, \dots, G_m)$  then  $R_{k+1} = \langle C_k \# \sim G_i; I_k \rangle$  for some  $1 \leq i \leq m$ .

**D3.** if  $F_k = G$  and  $G \notin I_k$  then for some rule  $G \leftarrow B_1, \dots, B_m \in \Pi$ ,  $R_{k+1} = \langle C_k \# G \# (B_1, \dots, B_m); I_k \cup \{G\} \rangle$

**D4.** if  $F_k = (g, G)$  then  $R_{k+1} = \langle C_k \# G; I_{gk} \rangle$  if there is a derivation from  $\langle C_k \# g; I_k \rangle$  to  $\langle L \# t; I_{gk} \rangle$ .

There is a *WFM*-derivation for  $G$  in  $\Pi$  iff there is a sequence from  $\langle \{\} \# G; \{\} \rangle$  to  $\langle L \# t; I \rangle$ , for some  $I$ .

We argue these rules are intuitive when one recalls the definition of 3-valued model [cf. section 2]: rule D1.1 establishes the *CWA*<sup>3</sup>. Rule D1.2 says that a literal may support on itself when proving its falsity<sup>4</sup>. Rule D2.1 says that for an atom to be interpreted as false it has to be proven false in all definitions for it. Rule D2.2 says that for a body of a rule to be false it is enough to prove some literal in the body to be false<sup>5</sup>. Rule D3 says that for a literal to be true it is enough to have a rule with all body literals true<sup>6</sup>. Rule D4 says that a conjunction of formulas is true if each element is true. Note that  $I_k = \bigcup_{i \leq n} I_i \cup \{F_k\}$  if  $F_k$  is a literal. This means we don't need to explicitly record  $I_k$  at each step  $k$  but simply consider all the  $C_j$  in ( $j < k$ ). Note that rule D4 introduces a notion of sub-derivation. We now present examples illustrating the application of the derivation rules.

**Example 1** For the program  $\Pi = \{p \leftarrow \sim q\}$ , a *WFM*-derivation for  $p$  is:

$$\begin{array}{ll} \{\} \# p & \\ \{p\} \# \sim q & D3 \\ \{p, \sim q\} \# t & D1.1 \end{array}$$

**Example 2** Let  $\Pi$  be the "work-tired" example [Przymusiński, 1990] with the obvious abbreviations:

$$\begin{array}{ll} w \leftarrow t & (1) \\ t \leftarrow \sim s & (2) \\ s \leftarrow \sim w & (3) \\ a \leftarrow w, \sim p & (4) \\ p & \end{array}$$

A failed derivation for  $\sim a$  is:

$$\begin{array}{ll} \{\} \# \sim a & \\ \{\sim a\} \# \sim(w, \sim p) & D2.1 \text{ and } (4) \\ \{\sim a\} \# \sim w & D2.2 \\ \{\sim a \sim w\} \# \sim(\sim t) & D2.1 \text{ and } (1) \\ \{\sim a \sim w\} \# t & D2.2 \text{ and } \sim(\sim t) = t \\ \{\sim a \sim w, t\} \# \sim s & D3 \text{ and } (2) \\ \{\sim a \sim w, t, \sim s\} \# w & D2.2, D2.1 \text{ and } \sim(\sim w) = w \text{ and } (3) \\ & \text{failure to continue} \end{array}$$

<sup>3</sup>Note that according to the second point of the definition of the  $\Psi^*$  operator, if an atom  $A$  has no rules in  $\Pi$ , then  $\Psi^*(I)(A) = 0$  for all interpretations  $I$  of  $P$ .

<sup>4</sup>According to the definition of  $\Psi^{*\uparrow w}$ , we start with  $\Psi^{*\uparrow 0} = \langle \{\}, \mathcal{H} \rangle$ . So every negative literal may depend on itself. There is no corresponding rule for positive literals

<sup>5</sup>Again these two rules follow exactly the second point of definition 2.6

<sup>6</sup>This is what is stated in the first point of the definition of  $\Psi^*$

and a successful derivation for  $\sim a$ :

$$\begin{array}{ll} \{\} \# \sim a & \\ \{\sim a\} \# \sim(w, \sim p) & D2.1 \text{ and } 4 \\ \{\sim a\} \# p & D2.2, D2.1 \text{ and } \sim(\sim p) = p \text{ and } (4) \\ \{\sim a, p\} \# t & D3 \end{array}$$

**Example 3** There is no derivation for  $(p, q)$  in program  $\Pi = \{p \leftarrow \sim q, q \leftarrow \sim p\}$ .

$$\begin{array}{ll} \{\} \# (p, q) & I_0 = \emptyset \\ \{\} \# p & I_1 = \emptyset \\ \{p, \sim q\} \# p & I_3 = \{p, \sim q\} \text{ failure} \end{array}$$

Note that even the selected literal order differed the derivation definition is still applicable because we keep a record of  $I_k$  at each derivation step.

### 3.1 WFM-Trees

A derivation from  $\langle \emptyset \# G; \emptyset \rangle$  to  $\langle L \# t; I \rangle$  may be interpreted as the construction of certain trees to be introduced now. These trees are obtained from the derivation rules with the following in mind: at each derivation step  $\langle C_k \# L_k; I_k \rangle$ ,  $C_k$  is the ordered ancestor list of literal  $L_k$  which is a node of the tree, and  $I_k$  is the set of all literals in the nodes already visited by the derivation procedure. In the following we will omit the special symbol  $t$ .

**Definition 3.5 (WFM-Tree)** A *WFM-tree* for  $G$  given program  $\Pi$  *WFM*( $G, \Pi$ ) is a finite tree with root  $G$ , such that if  $N$  is the literal of a node of the tree then:

**WFM-I** If  $N$  is negative, let  $N = \sim L$  and:

- 1) if there are no rules for  $L$  then  $N$  is a leaf (rule D1.1)
- 2) if  $\sim L$  has an identical ancestor  $A$  and all literals in the branch from  $\sim L$  to  $A$  are negative then  $N$  is a leaf (rule D1.2)
- 3) if there are  $r$  rules for  $L$ : (rules D2.1+D2.2)

$$\begin{array}{l} L_1 \leftarrow B_{11}, \dots, B_{k1} \\ \dots \\ L_r \leftarrow B_{1r}, \dots, B_{kr} \end{array}$$

in  $\Pi$ , then node  $\sim L$  has  $r$  immediate descendants  $\sim B_{j1}, \dots, \sim B_{hr}$ , each one selected from the body of a different rule.

**WFM-II** If  $N$  is positive then:

- 1) If there is a fact  $N$  in  $\Pi$ , then  $N$  is a leaf (rule D3)
- 2) the  $n$  immediate descendants are those literals  $B_1 \dots B_n$ , such that a rule  $N \leftarrow B_1, \dots, B_n$  exists in  $\Pi$  (rule D4)

By considering all possible choices of rules and literals all *WFM*-trees are obtained.

**Proposition 3.1** For every program  $\Pi$  and goal  $G$  there is a *WFM*-derivation for  $G$  in  $\Pi$  iff there is a *WFM-Tree*( $G, \Pi$ ).

Note that a context  $C$  in a  $C$ -formula  $C \# L$ , expresses a branch from the root of the tree to node  $L$ . Given a tree and a node, its context is implicitly defined by the ordered set of its ancestors, with its father being the

most recent one in  $C$  (the rightmost). The condition  $G \notin I_k$  in D2.1 and D3 means that if a tree has a node  $L$  (resp.  $\sim L$ ) then it may have no node  $\sim L$  (resp.  $L$ ).

We may think of the derivation rules as stating conditions for re-writing a literal, possibly by cancelation with a previous ancestor in the tree. For the well founded model derivation procedure the only possible cancelation of a literal with an ancestor is provided by rule D1.2.

**Example 4** The *WFM-Tree* for  $p$  given program  $\{p \leftarrow \sim q\}$  is:

**Example 5** The *WFM-Tree* for  $\sim a$  for the program below is:

**Example 6** The *WFM-Tree* for  $\sim a$  for the program below is:

Note the *WFM* of this program is  $\{\sim a, \sim r, \sim q\}$ .

### 3.2 Properties of *WFM-Trees*

By definition *WFM-Trees* are finite. The only type of leaf nodes in a *WFM-tree* are:

- 1) a positive literal with no identical ancestor
- 2) a negative literal with no identical ancestor
- 3) a negative literal with an identical ancestor

**Proposition 3.2** Every branch from the root literal has at most one node with an identical ancestor.

**Proposition 3.3** If a leaf node for literal  $L$  has an identical ancestor then  $L$  is a negative literal.

**Proposition 3.4** If a leaf node for literal  $L$  has no identical ancestor and is a negative literal  $L = \sim H$  then there are no rules for  $H$  in  $\Pi$ .

**Proposition 3.5** If a leaf node has a positive literal  $L$  then no node in the branch from the root literal to  $L$  has an identical ancestor literal, and there is a fact  $L$  in program  $\Pi$ .

**Lemma 3.1** (*Leaves are in the WFM*) If  $T$  is a *WFM*( $G, \Pi$ ) tree for  $G$  in  $\Pi$  then:

- 1) a positive literal which is in a leaf node, and has no identical ancestor, is in *WFM*( $\Pi$ )
- 2) a negative literal which is in a leaf node, and has no identical ancestor, is in *WFM*( $\Pi$ )

3) a negative literal which is in a leaf node, and has an identical ancestor is in *WFM*( $\Pi$ )

**Proof:**

- 3.1.1) if a positive literal  $L$  is in a leaf node, and has no identical ancestor, then there is a fact  $L$  in  $\Pi$  and facts are always in *WFM*( $\Pi$ ).
- 3.1.2) if a negative literal  $\sim L$  is in a leaf node, and has no identical ancestor, then there are no rules for  $L$  in  $\Pi$ . For an atom  $L$  such that no rules for it exist in  $\Pi$ ,  $\sim L$  is in *WFM*( $\Pi$ ).
- 3.1.3) if a negative literal  $\sim L$  is in a leaf node and has an identical ancestor, we have:

i.e. there is at least one chain from  $L$  to  $L$ , and possibly a rule for  $L$ , such as (3) in the program below:

- (1)  $L \leftarrow \dots H \dots$
- (2)  $H \leftarrow \dots L \dots$
- (3)  $L \leftarrow B_1 \dots B_n$

i.e. in  $\Pi$  there is a chain of positive literals  $L \dots H \dots L$ , and the well founded model contains  $\sim L \dots \sim H \dots \sim L$ .

Note that for the model not to contain  $\sim L$  by (3) all  $B_i$  would have to differ from false. But in that case the tree named  $B_i$  in the figure above could not exist, nor the father node  $\sim L$ .

**Lemma 3.2** Given a *WFM-tree* for  $G$  then, for any internal node literal  $H$ , if its immediate descendents  $D_1 \dots D_n$  are in the well founded model, then  $H$  is in the *WFM*.

**Proof:** The proof follows easily from the observation that the only tree formation rules introducing descendents nodes are *WFM-I.3* and *WFM-II.2* and the definition of 3-valued interpretation (cf. footnotes 5 and 6).

**Theorem 3.3** (*Soundness of WFM-Trees*) Let  $\Pi$  be a program and  $L$  a literal. If there is a *WFM-tree* for  $L$  then  $L$  is in *WFM*( $\Pi$ ).

**Proof:** Follows directly from lemma 3.1 and lemma 3.2 above.

**Corollary 1** Given program  $\Pi$  and literal  $G$  such that  $G \in \text{WFM}(\Pi)$  then all literals in the *WFM*( $G, \Pi$ ) are in *WFM*( $\Pi$ ).

**Theorem 3.4** (*Completeness of WFM trees*) Let  $\Pi$  be a program and  $L$  a literal. If  $L$  is in *WFM*( $\Pi$ ) there is a *WFM-tree* for  $L$ .

**Proof:** Appears in the extended version.

## 4 Stable Models

We present now a derivation procedure such that, given a program  $\Pi$  and a literal  $G$ , the derivation succeeds if  $G$  is in some  $XSM(\Pi)$ .

### Definition 4.1 ( $XSM$ -Derivation)

Let  $R_j = \langle C_j \# F_j; I_j \rangle$  where  $C_j$  is a context and  $I_j$  a set of literals. A  $XSM$ -derivation from  $R_i$  to  $R_n$  is a sequence from  $\langle C_i \# F_i; I_i \rangle$  to  $\langle C_n \# F_n; I_n \rangle$  such that for any  $\langle C_k \# F_k; I_k \rangle$  ( $i \leq k \leq n$ ) the following derivation rules apply (where we assume  $C_{k+1} = C_k$  and  $I_{k+1} = I_k$  unless stated otherwise):

**D1.1** if  $F_k = \sim G$  and there is no rule  $G \leftarrow B$  then  $R_{k+1} = \langle C_k + \sim G \# t; I_k \cup \{\sim G\} \rangle$

**D1.2** if  $F_k = \sim G$  and  $\sim G \in C_m$ ,  $m \leq k$  then  $F_{k+1} = t$

**D2.1** if  $F_k = \sim G$ ,  $\sim G \notin C_k$ ,  $G \notin I_k$ , and there are  $r$  rules for  $G$  with  $G_i$  as head

$$\begin{aligned} G_1 &\leftarrow B_{11}, \dots, B_{m1} \\ &\dots \\ G_r &\leftarrow B_{1r}, \dots, B_{m'r} \end{aligned}$$

in  $\Pi$  then  $C_{k+1} = C_k + \sim G \# \tilde{G}_1, \dots, \tilde{G}_r$ , and  $I_{k+1} = I_k \cup \sim G$  where  $\tilde{G}_i$  is a short hand for  $\sim(B_{1i}, \dots, B_{mi})$

**D2.2** if  $F_k = \sim(G_1, \dots, G_m)$  then

$$R_{k+1} = \langle C_k \# \sim G_i; I_k \rangle \text{ for some } 1 \leq i \leq m$$

**D3.1** if  $F_k = G$ ,  $\sim G \notin I_k$  and  $G \notin I_k$  then for some rule  $G \leftarrow B_1, \dots, B_m$  in  $\Pi$ ,  $R_{k+1} = \langle C_k + G \# (B_1, \dots, B_m); I_k \cup \{G\} \rangle$

**D3.2** if  $F_k = G$  and  $G \in C_m$  ( $m < k$ ) then  $F_{k+1} = t$

**D4** if  $F_k = (g, G)$  then  $R_{k+1} = \langle C_k \# G; I_{gk} \rangle$  if there is a derivation from  $\langle C_k \# g; I_k \rangle$  to  $\langle L \# t; I_{gk} \rangle$ .

Note these derivation rules include, as expected, those for well  $WFM$ -derivations.

### Example 7

$$\begin{aligned} a &\leftarrow \sim b & (1) \\ b &\leftarrow \sim a & (2) \end{aligned}$$

A  $XSM$ -derivation for  $a$  is as follows:

$$\begin{aligned} \{\} \# a & \\ \{a\} \# \sim b & \text{ D3.1 and (1)} \\ \{a \sim b\} \# a & \text{ D2.1 and D2.2 and } \sim(\sim a) = a \text{ and (2)} \\ \{a \sim b\} \# t & \text{ D3.2} \end{aligned}$$

The  $XSM$ -derivation for  $\sim a$  is as follows:

$$\begin{aligned} \{\} \# \sim a & \\ \{\sim a\} \# b & \text{ D2.1 and D2.2 and } \sim(\sim b) = b \text{ and (1)} \\ \{\sim ab\} \# \sim a & \text{ D3.1 and (2)} \\ \{\sim ab\} \# t & \text{ D1.2} \end{aligned}$$

### 4.1 $XSM$ -trees

**Definition 4.2 ( $XSM$ -tree)** A  $XSM$ -tree for  $G$  given program  $\Pi$ ,  $XSM(G, \Pi)$  is a finite tree with root  $G$ , such that if  $N$  is the literal of a node of the tree then:

**XSM-I** If  $N$  is negative, then  $N = \sim L$  and:

- 1) if there are no rules for  $L$  then  $N$  is a leaf (rule D1.1)

- 2) if  $\sim L$  has an identical ancestor  $A$  and all literals in the branch  $\sim L$  to  $A$  are negative then  $N$  is a leaf (rule D1.2)

- 3) if there are  $r$  rules for  $L$ : (rules D2.1+D2.2)

$$\begin{aligned} L_1 &\leftarrow B_{11}, \dots, B_{k1} \\ &\dots \\ L_r &\leftarrow B_{1r}, \dots, B_{k'r} \end{aligned}$$

in  $\Pi$ , then node  $\sim L$  has  $r$  immediate descendants  $\sim B_{j1} \dots \sim B_{hr}$ , each one selected from the body of a different rule

- 4) if  $\sim L$  has an identical ancestor  $A$  with some positive literal in between, then  $N$  is a leaf (rule D1.2)

**XSM-II** If  $N$  is positive then:

- 1) if there is a fact  $N$  in  $\Pi$ , then  $N$  is a leaf (rule D3.1)
- 2) the  $n$  immediate descendants are those literals  $B_1 \dots B_n$ , such that a rule  $N \leftarrow B_1 \dots B_n$  exists in  $\Pi$  (rule D4)
- 3) if  $N$  has an identical ancestor  $A$ , with some negative literal in between, then  $N$  is a leaf (rule D3.2)

A  $XSM$ -Tree has two types of leaves not appearing in the  $WFM$ -Tree, namely: *i*) positive literal leaf nodes having an identical ancestor and with some negative literal in between; and *ii*) negative literal leaf nodes having an identical ancestor and with some positive literal in between.

**Example 8** Although the program  $\{a \leftarrow \sim b; b \leftarrow \sim a\}$  has no  $WFM$ -Tree it has the following  $XSM$ -Trees (among others):

The soundness proof is similar to that of  $WFM$ -Trees, but the equivalent to lemma 3.1 is now:

**Lemma 4.1** (*Leaves are in the  $XSM$* ) If  $T$  is a  $XSM$  tree for  $G$  then:

- 4.1.1) a positive literal in a leaf node, having no identical ancestor, is in some  $XSM(\Pi)$
- 4.1.2) a negative literal in a leaf node, having no identical ancestor, is in some  $XSM(\Pi)$
- 4.1.3) a negative literal in a leaf node, having an identical ancestor, is in some  $XSM(\Pi)$
- 4.1.4) a positive literal in a leaf node, having an identical ancestor and some negative literal in between, is in some  $XSM(\Pi)$
- 4.1.5) a negative literal in a leaf node, having an identical ancestor and some positive literal in between, is in some  $XSM(\Pi)$

**Proof:** Proof of 1,2 and 3 4.1.i, 4.1.ii and 4.1.iii follows from lemma 3.1 and the fact that all literals in the  $WFM(\Pi)$  are in all  $XSM(\Pi)$ .

The completeness proof may be found in the full version.

## 5 A Prolog implementation

We present here a Prolog implementation of the above procedures which provides them with an operational semantics. Lines are numbered for referencing. The interpreter is basically the implementation of the derivation rules of the procedures [cf. section 3 and 4] plus loop checking. Thus the execution always terminates. The code may be used for *WFM*-derivations as below, or for *XSM*-derivations by deleting line (7.4).mb is the member predicate.

```
s(~((G1,G)),I,0,An) :- s(~G1,I,0,An). (1)
s(~((G1,G)),I,0,An) :-!,s(~(G),I,0,An). (2)
s((G1,G),I,0,An):-!,s(G1,I,II,An),s(G,II,0,An). (3)
s(~(G),A,B,C):-!,s(G,A,B,C). (4)
s(~G,I,_,An):-mb(G,I),!,fail. (5)
s(G,I,_,An):-G~(.),mb(~G,I),!,fail. (6)
s(G,I,[G|I],An):-d(G,An,D), (7)
    (D=z,G=(~),!,D=z,!,fail;
    D=e,!,fail;% wfm (7.4)
    D=e,!).
s(~G,_,_,_) :- (G<<-),!,fail. (8)
s(~G,I,0,An) :-!,findall((G<<-B),(G<<-B),L), (9)
    all_out(~G,L,[~G|I],0,[~G|An]).
s(G,I,[G|I],An) :- (G<<-). (10)
s(G,I,0,An) :- (G<<-B),s(B,[G|I],0,[G|An]).(11)

all_out(~G,[],I,I,An). (12)
all_out(~G,[(G<<-B1)|Gn],I,0,An) :- (13)
    s(~(B1),I,II,An),all_out(~G,Gn,II,0,An).

d(~G,[(~X)|An],D) :-!,d(~G,[(~X)|An],e,ZNZ,D).
d(~G,[X|An],D):-!,d(~G,[X|An],o,ZNZ,D).
d(G,[(~X)|An],D):-!,d(G,[(~X)|An],o,ZNZ,D).
d(G,[X|An],D):-d(G,[X|An],e,ZNZ,D).
d(G,[G|T],e,Z,z):-var(Z),!.
d(G,[G|T],D,nz,D):-!.
d(G,[(~.),(~X)|T],EO,Z,D):-!,d(G,[(~X)|T],EO,Z,D).
d(G,[(~.),X|T],e,_,D):-!,d(G,[X|T],o,nz,D).
d(G,[(~.),X|T],o,_,D):-!,d(G,[X|T],e,nz,D).
d(G,[_,(~X)|T],e,_,D):-!,d(G,[(~X)|T],o,nz,D).
d(G,[_,(~X)|T],o,_,D):-!,d(G,[(~X)|T],e,nz,D).
d(G,[_ ,X|T],EO,Z,D):-d(G,[X|T],OE,Z,D). (25)
```

Lines (1)-(2) correspond to rule D2.2. Line (3) corresponds to rule D4. Line (4) is obvious. Lines (5)-(6) ensure the condition  $G \notin I_k$ . Lines (9), (12) and (13) correspond to D2.1. Lines (14) - (25) do an ancestor search for literal  $G$ : the result of this search can be: the literal  $G$  has an ancestor node in the current context ( $D=z$ ); the literal  $G$  has an ancestor node in some context other than the current one; the literal  $G$  has no ancestor goal and the predicate `dist/3` in rule (7) fails. Line (7.2) corresponds to derivation rule D1.2. Line (7.5) corresponds to rules D1.2 and D3.2. Line (12) accounts for rule D1.1. Line (7.3) avoids the potential loop of a positive literal  $G$  with an identical ancestor  $G$  with no negative literals in between. A literal  $G$  is in *WFM*(II) (resp. *XSM*(II)) if the query `?- s(G, [], L, [])` succeeds. The procedure returns in  $L$  a set of literals in the *WFM*(II) (resp. *XSM*(II)).
